23

Claims 1-66 stand rejected under 35 U.S.C.§103(a) as being unpatentable over U.S. Patent No. 6,230,318 (Halstead et al.) in view of U.S. Patent No. 6,598,166 (Folmsbee).

Applicants respectfully traverse these rejections for at least the following reasons.

To establish a *prima facie* case of obviousness, three basic criteria must be met. First, there must be some suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings. Second, there must be a reasonable expectation of success. Finally, the prior art reference (or references when combined) must teach or suggest all the claim limitations.

# Regarding the Cited References:

Halstead et al. disclose an application program that is constructed from a collection of individual reusable tools that are arranged in a tree structure. When the application is initiated, a corresponding current configuration file is followed to construct the application from the various tools. This allows for changes and upgrades to be more easily implemented.

Note that Halstead et al. deliver the application as a set of tools and a current configuration file, and therefore the application is in a fully functional

5 · 6

10

12

13 14

16 17

18

20

21 22 23

24

25

condition. Furthermore, Halstead et al. are silent as to and therefore do not teach any encryption/decryption processes.

Folmsbee discloses a special microprocessor that successfully changes its operating logic to run scrambled software op-codes without requiring decryption keys and/or decryption capabilities. Here, the software's op-codes are scrambled based on an encryption key during compile by a first computer. The resulting scrambled software includes corresponding logic instructions. The corresponding logic instructions allow another computer having a special microprocessor with reconfigurable logic to then be properly reconfigured to run the scrambled software op-codes without ever having to first decrypt them.

Note that the scrambled software op-codes and related logic instructions are delivered in a fully functional condition to the special microprocessor, the scrambled software op-codes are not rearranged instead the special microprocessor logic is reconfigured, and the special microprocessor does not receive a decryption key. Indeed, one of the motivations for *Folmsbee's* invention is that some computers are located in countries to which certain cryptographic technology cannot be legally imported.

## Regarding Claims 1-17:

Independent Claim 1 is directed towards a method that includes providing an initial digital good to at least one computer. As recited, the initial digital good includes a plurality of selectively arranged parts in an initial configuration that is configured so as to not properly function with the computer. This is very different than the cited art. Halstead et al. teach that the application that is delivered is in a fully functional condition. Similarly, in Folmsbee the scrambled software op-

codes and related logic instructions are delivered in a fully functional condition for the special microprocessor. Therefore, neither *Halstead et al.* and/or *Folmsbee*, alone or in combination, disclose or reasonable suggest providing an initial digital good having a plurality of selectively arranged parts in an initial configuration that will not properly function with the computer as specifically recited in Claim 1.

The method of Claim 1 further includes, with the computer, receiving unique key data. This too not found in the cited art. Halstead et al. do not even mention or allude to encryption/decryption or key data. Folmsbee is solving the very problem of not wanting to send key data to the remote computer. That is why Folmsbee scrambles the op codes and rearranges the logic of the special microprocessor. Hence, it is clear that neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest receiving unique key data as specifically recited in Claim 1.

Moreover, the method in Claim 1 further recites converting the initial digital good into a modified digital good using the unique key data to selectively individualize the initial digital good for use with the computer, such that the plurality of selectively arranged parts in the modified digital good have been rearranged to have a substantially unique operative configuration that properly functions with the computer and is different than the initial configuration. This is also very different than that which is taught by the cited art. Halstead et al. does not mention key data and instead configures a set of tools based on a configuration file. Folmsbee is solving the very problem of not wanting to send key data to the remote computer. That is why Folmsbee not only teaches away from using key data, but also teaches that the scrambled software op-codes are not even rearranged by the computer. Instead, Folmsbee teaches that the special microprocessor logic

14

16

17

19 20

22 23

24

25

21

is reconfigured based on corresponding logic instructions. Therefore, it is clear that neither *Halstead et al.* and/or *Folmsbee*, alone or in combination, disclose or reasonable suggest converting the initial digital good into a modified digital good using the unique key data in the manner as specifically recited in Claim 1.

The Office Action has failed to establish a prima facie case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings to provide the method as recited in Claim 1. Secondly, there is no reasonable expectation of success in combining the cited references to somehow end up with the method as recited in Claim 1. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 1.

Thus, Claim 1 is patentable over *Halstead et al.* and/or *Folmsbee*, alone or in combination.

Consequently, with Claim 1 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 2-17 which depend there from and recite further limitations.

# Regarding Claims 18-26:

Independent Claim 18 is directed towards a computer-readable medium comprising computer-executable instructions for, with the at least one computer, receiving an initial digital good, wherein the initial digital good includes a plurality of selectively arranged parts in an initial configuration and the initial digital good is configured as to not properly function with the computer. This is very different than the cited art also. Halstead et al. teach that the application that is delivered is

 in a fully functional condition and Folmsbee teaches that the scrambled software op-codes and related logic instructions are delivered in a fully functional condition for the special microprocessor. As such, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest providing receiving an initial digital good that includes a plurality of selectively arranged parts in an initial configuration configured so as to not properly function with the computer as specifically recited in Claim 18.

Claim 18 also specifies receiving unique key data. This is not found in the cited art. Halstead et al. do not even mention or allude to encryption/decryption or key data and Folmsbee is dedicated to not sending or otherwise requiring the computer to have or use key data. Again, that is why Folmsbee scrambles the op codes and rearranges the logic of the special microprocessor. Hence, it is clear that neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest receiving unique key data as specifically recited in Claim 18.

Claim 18 further specifies converting the initial digital good into a modified digital good using the unique key data to selectively individualize the initial digital good for use with the at least one computer, such that the plurality of selectively arranged parts in the modified digital good are rearranged to have a substantially unique operative configuration that properly functions with the at least one computer and is different than the initial configuration. This is completely different than that which is taught by the cited art. Recall that Halstead et al. do not mention key data. Instead Halstead et al. configure a set of tools based on a configuration file. Since Folmsbee is solving the very problem of not wanting to send key data to the remote computer, Folmsbee clearly teaches away from using key data in the remote computer. Folmsbee teaches that logic is reconfigured tin

9 10

12 13

11

14

16

18

19

20

21 22

23 24 the remote computer based on certain instructions such that the scrambled software op-codes are functional. Consequently, neither *Halstead et al.* and/or *Folmsbee*, alone or in combination, disclose or reasonable suggest converting the initial digital good into a modified digital good using the unique key data in the manner as specifically recited in Claim 18.

Once again, the Office Action has failed to establish a prima facie case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings to provide the computer-readable medium as recited in Claim 18. Secondly, there is no reasonable expectation of success in combining the cited references to somehow end up with the clearly different steps as recited in Claim 18. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 18.

Thus, Claim 18 is patentable over *Halstead et al.* and/or *Folmsbee*, alone or in combination.

Consequently, with Claim 18 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 19-26 which depend there from and recite further limitations.

### Regarding Claims 27-33:

Independent Claim 27 is directed towards a computer-readable medium comprising computer-executable instructions for receiving unique identifier data associated with at least one computer. Such is not even mentioned in the cited art. Halstead et al. do not mention or require any unique identifier data associated with

APR 16 2004 09:11 FR LEE - HAYES

11

12

16

19

22

a computer. Similarly, Folmsbee does not mention or require any unique identifier data such as this. Therefore, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest this limitation as specifically recited in Claim 27.

Claim 27 further states generating unique key data based on at least the unique identifier data. Since *Halstead et al.* do not mention or require any unique identifier data associated with a computer and *Folmsbee* does not mention or require any unique identifier data, neither of these references then go on to somehow generate unique key data as recited in Claim 27.

Claim 27 also states receiving at least a portion of an initial digital good having a plurality of selectively arranged parts in an initial configuration, converting the at least a portion using the unique key data to selectively individualize the portion, such that a modified portion of the digital good is produced having the plurality of parts rearranged in a different configuration than the initial configuration. This is also unlike the cited references. As described above neither Halstead et al. nor Folmsbee utilize unique key data in this manner. Halstead et al. is silent with regard to encryption/decryption. While Folmsbee uses an encryption key to scramble op codes, the remote computer does not unscramble the op codes with a decryption key. In fact, Folmsbee does not want the remote computer to need such a key. So, instead, Folmsbee provides instructions to the remote computer which cause the special microprocessor therein to reconfigure its logic in a manner that will then allow the scramble op codes to function properly. Thus, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest using unique key data as specifically recited in Claim 27.

Claim 27 further states, providing at least the modified portion of the digital good and at least a portion of the unique key data to the at least one computer. As described above, the cited art fails to create such a modified portion of such a digital good and/or such unique key data. Thus, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest this step as specifically recited in Claim 27.

The Office Action has failed to establish a prima facie case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings to provide the recited steps and limitations as recited in Claim 27. Secondly, there is no reasonable expectation of success in combining the cited references to somehow end up with the recited limitations in Claim 27. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 27.

Thus, Claim 27 is patentable over *Halstead et al.* and/or *Folmsbee*, alone or in combination.

As such, with Claim 27 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 28-33 which depend there from and recite further limitations.

#### Regarding Claims 34-42:

Independent Claim 34 is drawn to an apparatus for use in a host computer. The recited apparatus includes an individualizer that is configured to receive unique key data. This is completely different than that which is taught by the cited art. Recall that *Halstead et al.* do not mention key data and *Folmsbee* teaches

5

9

11

12

7

13

15

16

18

19 20

21

22 23

24

away from transferring any such key data between computers. Consequently, neither *Halstead et al.* and/or *Folmsbee*, alone or in combination, disclose or reasonable suggest an individualizer and unique key data as specifically recited in Claim 34.

Claim 34 further states that the individualizer is also configured to receive at least a portion of an initial digital good that includes a plurality of selectively arranged parts in an initial configuration, and produce at least a portion of a modified digital good using the unique key data to selectively individualize the initial digital good for use with the host computer, and that the plurality of selectively arranged parts in the modified digital good are rearranged to be operatively different in configuration than the initial configuration of the digital good. This is also much different than that which is taught by the cited art. Halstead et al. teach that the set of tools are configured according to configuration file. Halstead et al. fail to disclose or suggest that unique key data can used to selectively individualize the initial digital good for use with the host computer. The configuration file in Halstead et al. only specifies how the tools should be setup based on the latest updates. Folmsbee also does not use unique key data in the host computer as that is exactly what he is trying to avoid having to do. Moreover, Folmsbee teaches that it is the logic in the special microprocessor that is reconfigured in the host computer and not the scrambled op codes. Further, the logic is not reconfigured using unique key data, but rather in accord with the instructions received with the scrambled op codes. Thus, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest converting the initial digital good into a modified digital good using the unique key data in the manner as specifically recited in Claim 34.

7

13

14

17 18

16

202122

24

23

Here again, the Office Action has failed to establish a *prima facie* case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings to provide the claimed individualizer of Claim 34. Secondly, there is no reasonable expectation of success in combining the cited references to somehow end up with the very different apparatus as recited in Claim 34. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 34.

Thus, Claim 34 is patentable over *Halstead et al.* and/or *Folmsbee*, alone or in combination.

With Claim 34 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 35-42 which depend there from and recite further limitations.

## Regarding Claims 43-49:

Independent Claim 43 is directed towards an apparatus for use in a source computer. Here, the recited apparatus includes a key generator configured to receive a unique identifier data from a destination computer and generate unique key data based on the received unique identifier data associated with the destination computer. The cited art is again very different. Halstead et al. do not mention or require any unique identifier data associated with a destination computer. Also, Halstead et al. do not even mention generating such key data. Folmsbee does not mention or require any unique identifier data such as this. Indeed the encryption key that is used to scramble op codes in Folmsbee is specifically n t related to the destination computer, since it is the goal of Folmsbee

9

12

13

14

16

17

20 21

19

23 24

25

22

to avoid having to provide a decryption key to the destination computer. Furthermore, Folmsbee fails to even suggest that the resulting scrambled op codes are scrambled in some specific manner for a particular destination computer. Therefore, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest this limitation as specifically recited in Claim 43.

PLL

Claim 43 further states that the apparatus includes an individualizer configured to receive the unique key data and at least a portion of an initial digital good having a plurality of selectively arranged parts in an initial configuration and output at least a portion of a modified digital good using the unique key data to selectively individualize the initial digital good, such that in the modified digital good the plurality of selectively arranged parts have been rearranged to have an operatively different configuration than the initial configuration. This too is different than that which is taught by the cited art. Halstead et al. do not mention key data and do not therefore use it in this manner. While Folmsbee use an encryption key to scramble op codes the key is not unique in the way that this generated unique key data is as recited in this claim (see previous paragraph). Further, Folmsbee is scrambling op codes and generating corresponding instructions for reconfiguring the logic in a special microprocessor. That is not what is being done here. Thus, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest converting the initial digital good into a modified digital good using the unique key data in the manner as specifically recited in Claim 43.

Once again, the Office Action has failed to establish a *prima facie* case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the

12

13

9

16

19

17

22

23 24 art, to modify the reference or to combine reference teachings to provide the claimed apparatus for use in a source as in Claim 43. Secondly, there is no reasonable expectation of success in combining the cited references to somehow end up with the novel apparatus as recited in Claim 43. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 43.

Thus, Claim 43 is patentable over *Halstead et al.* and/or *Folmsbee*, alone or in combination.

With Claim 43 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 44-49 which depend there from and recite further limitations.

#### Regarding Claims 50-66:

Independent Claim 50 is drawn to a system that includes an identifier configured to output unique identifier data associated with a computer. The cited art is again very different. Halstead et al. do not mention or require outputting or otherwise using any unique identifier data associated with a computer. Therefore, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest this limitation as specifically recited in Claim 50.

Claim 50 also recites that the system includes a key generator coupled to receive the unique identifier data and configured to generate at least one unique key data based on the received unique identifier data. The cited art is very different since the references fail to use unique identifier data. Halstead et al. do not even mention key data let alone generating such unique key data based on unique identifier data. Folmsbee also fails to even mention generating such unique key data or such unique identifier data. Instead Folmsbee just uses a

5

9

10

11

14

15

13

16

17

18

20

21 22

23 24 25 conventional encryption key to scramble op codes. Therefore, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest this limitation as specifically recited in Claim 50.

Claim 50 further specifies that the individualizer is configured to receive the unique key data and at least a portion of an initial digital good that includes a plurality of selectively arranged parts in an initial configuration, and output at least a portion of a modified digital good using the unique key data to selectively individualize the initial digital good, such that the plurality of selectively arranged parts in the modified digital good have been rearranged to be operatively different in configuration than the initial configuration of the digital good. This too is different than that which is taught by the cited art. Halstead et al. do not mention key data and do not therefore use it in this manner. While Folmsbee use an encryption key to scramble op codes the key is not unique in the way that this generated unique key data is as recited in this claim (see previous two paragraphs). Further, Folmsbee is scrambling op codes and generating corresponding instructions for reconfiguring the logic in a special microprocessor. That is not what is being done here. As such, neither Halstead et al. and/or Folmsbee, alone or in combination, disclose or reasonable suggest converting the initial digital good into a modified digital good using the unique key data in the manner as specifically recited in Claim 50.

The Office Action has therefore failed to establish a prima facie case of obviousness. First, there is no suggestion or motivation, either in the references themselves or in the knowledge generally available to one of ordinary skill in the art, to modify the reference or to combine reference teachings to provide the claimed system as in Claim 50. Secondly, there is no reasonable expectation of

15

17

18

20

22

23

24 25

LEE & HAYES, PLAC

success in combining the cited references to somehow end up with the novel system as recited in Claim 50. Finally, the references when combined clearly fail to teach or suggest all the limitations in Claim 50.

Thus, Claim 50 is patentable over Halstead et al. and/or Folmsbee, alone or in combination.

With Claim 50 being so clearly patentable over the cited art and in condition for prompt allowance, so too are Claims 51-66 which depend there from and recite further limitations.

### Conclusion

For at least these substantial reasons, it is respectfully requested that all of the rejections be reconsidered and withdrawn. The pending claims have been placed in condition for allowance and are clearly patentable over the cited art and should therefore be allowed.
